School of Physics and Astronomy University of Nottingham Nottingham, NG7 2RD ppxst5@nottingham.ac.uk

#### **Abstract**

This project aims to develop machine learning models to predict the speed and steering angle of images captured by Raspberry Pi cars. The project is divided into two parts: an online challenge and a live test. Multiple models with convolutional neural networks followed by fully connected layers were developed using transfer learning from pre-trained models. The models achieved a mean-squared-error of 0.009 in the public leaderboard and a mean-squared-error of 0.011 in the private leaderboard, and secured first place in the online challenge, demonstrating excellent predictive accuracy and generalisability. In the live test, the model successfully completed 90% of the tasks, including lane following and stop-on-object, though some challenges remain. Future studies could focus on enhancing data collection for better generalisability and upgrading Raspberry Pi cars' hardware for higher image resolution and greater model complexity.

# 1 Introduction

In the recent decade, autonomous driving has become one of the most rapidly advancing areas in the field of artificial intelligence (AI). Numerous companies have been founded with the goal of developing reliable self-driving systems [Law, 2023]. As the technology matures, hands-on experience has become more valuable for students and researchers to deepen their understanding of how real-world AI applications work.

One accessible platform for gaining such experience is PiCar [SunFounder]. PiCar is a small robot car that equipped with an onboard camera to capture forward-facing perspective of the car's environment, and a Raspberry Pi (RPi) single-board computer [RaspberryPi] for real-time computation. The captured image frames can be used as input to machine learning models running on the RPi that predict control signals, including steering angle and speed, of the car.

This project is divided into two phrases: an online challenge and a live test. In the online challenge, provided data were used to train the models for predicting the car's steering angle and speed of a given image. In the live test, models were trained on data collected by me, and the models were deployed to the PiCar to complete a variety of tasks to assess the model's performance.

The report is divided into five sections: introduction, methods, results, discussion, and conclusion. Section 2 (Methods), 3 (Results), and 4 (Discussion) are further divided into two subsections, corresponding to the online challenge and the live test phrase of the project.

## 2 Methods

In both phases of the project — the online challenge and the live test — the objective was to predict the PiCar's steering angle and speed from images captured by its onboard camera. Both control signals were normalised to the range [0, 1] using the following formulas [Lieu]:

$$\label{eq:anglenorm} \begin{split} \text{angle}_{\text{norm}} &= \frac{\text{angle} - 50}{80} \quad \text{where angle} \in [90 - 40, 90 + 40] = [50, 130] \\ \\ \text{speed}_{\text{norm}} &= \frac{\text{speed} - 0}{35} \quad \text{where speed} \in [0, 100] \end{split}$$

Here, the steering angle is centred at 90 (with a range of  $\pm 40$ ), and the recorded speed in the dataset is either 0 or 35. angle<sub>norm</sub> = 0 corresponds to a fully left turn, and  $\operatorname{angle}_{norm} = 1$  corresponds to a fully right turn. The normalised angles were restricted to steps of 1/16 = 0.0625, resulting in 17 possible angle values. Similarly, speed<sub>norm</sub> = 0 indicates the car stopped, and speed<sub>norm</sub> > 0 represents the car moved. Note that the PiCar is capable of running at any integer speed in range [0, 100], but only two speed values, 0 and 35, were used during the data collection period to restrict the normalised speed to either 0 (stop) or 1 (move).

## 2.1 Online challenge

The online challenge was assessed by the mean squared error (MSE) of a test dataset's private leaderboard, where a lower value indicated better model performance.

The steering angle model and the speed model were trained separately, to reduce the complexity of data preprocessing and modelling.

## 2.1.1 Training data

There were 13.8k RGB images of resolution 240 x 320 provided with the corresponding normalised labels [Lieu]. The dataset was noisy and included inaccurate labels, missing labels, and invalid image files. Figure 1 shows some examples of inaccurate labelling.

Figure 1: Examples of inaccurate labels in the dataset.

# 2.1.1.1 Data cleaning

In order to clean the dataset, first I wrote a Python script to read all the images, to handle errors, and to remove image files that caused errors. After that I ensured all the labels were within the range of [0, 1], and each record contained complete labels for both steering angle and speed.

#### 2.1.1.2 Data distribution

I visualised the data distribution in Figure 2. It shows that the distribution of steering angles is left-skewed and non-uniform, and the distribution of speeds is imbalanced, roughly 25:75.

# 2.1.1.3 Training set and test set

I split the data into training set and test set, with a ratio of 0.85 : 0.15, using explicitly defined random seeds to assure the reproducibility of the results, and the ratio between classes in both sets was approximately the same.

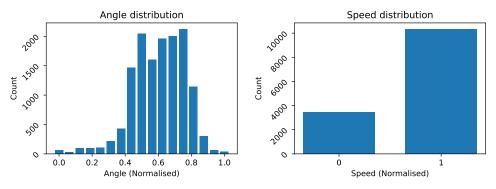

Figure 2: Distribution of steering angles and speeds in the dataset.

## 2.1.1.4 Data balancing

Given the severe class imbalance in steering angle, I applied a combination of oversampling and undersampling to the dataset, leading to a ratio between a minority and a majority class of approximately 0.22: 0.78. The above ratio was chosen carefully for several reasons:

- Oversampling too aggressively duplicated the minority classes too much, which led to overfitting.
- Undersampling too aggressively reduced the majority classes too much, which led to missing information of the majority class and underfitting.

After some experimenting, the above ratio turned out to be the best choice.

I left the speed dataset unchanged and used weighted loss to address the class imbalance instead, as it was not highly imbalanced.

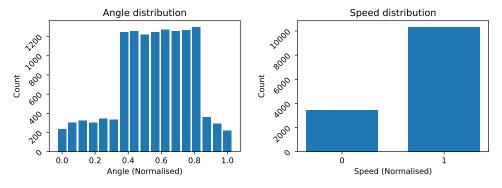

Figure 3: Distribution of steering angles and speeds after balancing.

## 2.1.1.5 Data augmentation

To increase the data variety and improve the generalisability of the model, I applied data augmentation to the training set to mimic real-world conditions, such as changes in lighting, movements of camera, and positioning of the PiCar. I augmented the images by applying the following settings randomly:

- Brightness scaled by factor in range [0.7, 1.3]
- Contrast scaled by factor in range [0.75, 1.25]
- Hue scaled by factor in range [0.95, 1.05]
- Saturation scaled by factor in range [0.7, 1.2]

- JPEG compression quality scaled by factor in range [0.8, 1.0]
- Rotation: [-5°, 5°]
- Crop to size of 210 x 280 randomly

, and resized the images back to the original size. Figure 4 shows some samples of the augmentation.

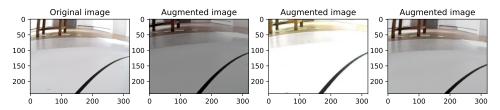

Figure 4: Samples of augmented images.

## 2.1.2 Modelling

Transfer learning was used to train the models. The base model for both the steering angle and speed models was pre-trained on MobileNetV3Large, which provided a good balance between feature extracting complexity and efficiency. The base model was frozen to prevent overfitting. Each model was followed by 10 heads - sub-models that took the features extracted from the base model as the input and outputted the steering angle or speed. These heads had different structures, which could include convolutional layers, global average pooling layer, flatten layer, fully connected layers, and dropout layers. The use of varied head architectures aimed to capture diverse features from the images, thereby increasing model generalisability and improving prediction accuracy.

Figure 5 and Figure 6 show the structure of the heads.

#### **2.1.2.1** Structures and hyperparameters

The structures of the heads were randomly created using the following rules:

- Number of convolutional layers: {0, 1, 2}
- Number of global average pooling layers: {0, 1}
- Number of flatten layers: 1 number of global average pooling layers
- Number of fully connected layers: {0, 1, 2, 3, 4}

Dropout layers were added based on observed overfitting during training.

The hyperparameters of the layers in the models were chosen and tuned manually based on observed training and test loss.

## **2.1.2.2** Training

The models were trained for 50 epochs with batch size of 64 and Adam optimiser with decaying learning rate:

$$\begin{aligned} \text{learning\_rate} &= \begin{cases} 0.02, & \text{if epoch} = 0 \\ \max\left(\frac{\text{initial\_learning\_rate}}{1 + \left(\frac{\text{epoch} - 1}{3}\right) \times \text{decay\_rate}}, 0.00015\right), & \text{otherwise} \end{cases} \\ \text{where initial\_learning\_rate} &= 0.01 \text{ and decay\_rate} = 0.4 \end{aligned}$$

The above decaying learning rate strategy aimed to keep the first epochs' learning rate high to improve convergence rate, while gradually decreased the learning rate to prevent overshooting.

The models were trained using the following loss functions:

- Steering angle model: Mean squared error
- Speed model: Weighted mean squared error

During the training of the steering angle models, the training data was randomly selected and augmented from the training set every epoch to reduce the risk of overfitting and introduce diversity of augmented images and undersampled classes.

#### 2.1.2.3 Prediction

To further increase the generalisability of the predictions, 4 models were trained with different random seeds for the train/test split. As a result, each image had  $4 \times 10 = 40$  predicted values for the steering angle and the speed. The predicted values were then averaged to obtain the prediction.

A threshold speed<sub>threshold</sub> was introduced to the speed prediction to reduce the mean squared error (MSE) and was tuned using the test set. The speed prediction was adjusted as follows:

$$\label{eq:adjusted speed prediction} \begin{aligned} \text{adjusted speed prediction} &= \begin{cases} 0.5 \times \text{sign}(\tilde{y}) + 0.5, & \text{if } |\tilde{y}| > \text{speed}_{\text{threshold}} \\ \tilde{y} + 0.5, & \text{otherwise} \end{cases} \\ &\text{where } \tilde{y} = \text{original speed prediction} - 0.5 \end{aligned}$$

A manual inspection was carried out on the predictions with high variance between the 40 predicted values to remove clearly incorrect predictions.
